Purpose

The purpose of this lab is to configure a PA-220 firewall with a small office/home office (SOHO) configuration. In general, SOHO firewalls will have to be configured to give IP addresses through Dynamic Host Configuration Protocol (DHCP) and translate addresses through Network Address Translation (NAT) in addition to filtering unsafe traffic. For the purposes of this lab, simultaneous internet connection and management of the firewall will be focused on, rather than filtering.

Background Information

Firewalls configured for small offices or home offices are important because they prevent attacks on the business. One viable way to have the firewall protect a company network is to just have it placed behind the company router. This way it allows for the firewall to inspect all traffic that goes through it. But this may not be the best location; another common location is to have the company router be behind the firewall.

Furthermore, having the PA-220 route for an office allows it to filter traffic differently from different VLANs or User-ID. This brings significant benefits in that it allows the PA-220 to do authentication, authorization, and accounting for the office network, ultimately keeping things secure.

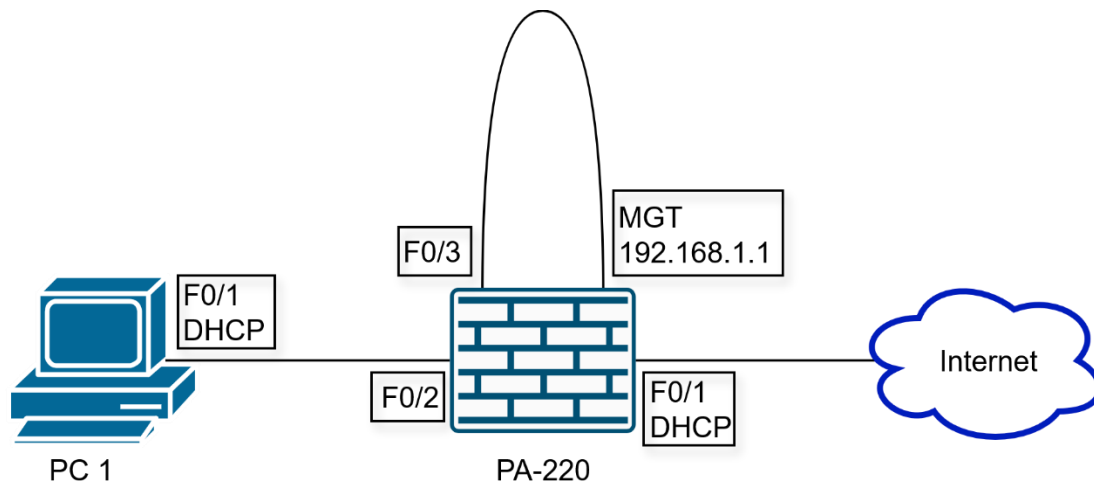

Some companies may need to have public facing servers (like web servers), while also having a private network in a company. The PA-220 can also logically separate these two using VLANs. One can have the public-facing servers in one VLAN and then have the private network on another VLAN. Another way to separate these two networks is to use different physical ports for the network. With these two options, the PA-220 allows flexibility in how someone wants to configure their firewall and security.

The PA-220, made by The Palo Alto Networks®, is a small NGFW made for small businesses and organizations. It has 8 ethernet ports, two power adapters for redundancy, a console port, and a management port. One interesting feature of the PA-220 is that it can detect hostile data even when the data is encrypted by TLS/SSL by decrypting that data. In addition to that, the PA-220 can integrate with Palo Alto Networks' cloud services. This allows the PA-220 to stop known attacks and malicious URLs from affecting devices on the network. There are many other notable features that the PA-220 has, but please refer to the PA-220 specs for the rest of them.

Lab Summary

In this lab, administrators will configure the PA-220 for a SOHO network. The PA-220 will do this by using DHCP to assign IP addresses to hosts and translating internal addresses to the internet (NAT). The PA-220 will act like an edge router to carry out the goals of this lab. In order to connect to the internet and manage the PA-220 through the PC, a piggy-back connection will be needed, since the management port cannot be internally routed through the PA-220. There are obvious security concerns of allowing this piggy-back connection, but it is only for testing, so if the admin disconnects the connection after configuring everything will operate securely.

Network Diagram with IP's

Problems

There were a few issues that were run into in this lab. One issue was confusion around where to find the VLAN *interface* configuration tab vs. the VLAN configuration tab. When I went to the VLANs section under network, I couldn't find anywhere to configure a VLAN interface, but after looking at Palo Alto documentation, I was able to find that VLAN interfaces were to be configured under the interfaces section (which makes sense in hindsight).

One other issue was the default virtual wire. Since the default virtual wire was no longer assigned to any interfaces after our configuration, the PA-220 was complaining about it when we were trying to commit changes. This issue was easily resolved by deleting the default virtual wire, since there was no need for it.

The last issue was a layer 1 issue. Because of the way the lab was set up, the traffic to the internet from our firewall had to go through many of the other internet switches placed around the lab. It turned out that one of the switches in the lab was misconfigured, dropping all of our internet traffic. This issue was really hard to solve, since we thought we had misconfigured the firewall when it was actually a problem with the lab. Later, we found that we couldn't even connect to the internet if directly connected to the internet switch, leading to us fixing the misconfigured internet switch.

Conclusion

The configuration of this PA-220 is important for any small business because of the need to filter traffic and prevent attacks in a company network. Through the steps outlined in this document any small company can configure their firewall to route devices to the internet, ensuring work goes smoothly for employees. Later, configuration of security policies will be needed to fully protect the company from attacks.
